Forever Model Indicator

Concept Introduction

Forever° Model [Pro+] ($niper) is a clean, structured framework for visualizing internal price behavior. It identifies shifts in market delivery by combining internal liquidity zones, divergence between correlated markets, and lower timeframe orderflow changes. Designed for repeatability, the model helps analysts build confidence through familiarity, not complexity.

Rather than attempting to forecast direction, this model focuses on recognizing recurring patterns in delivery behavior across timeframes. It does not issue alerts or predictions, but instead presents structured visual logic that can support manual analysis.

The model is stable, non-repainting, and built to highlight past setups once formed. It offers flexibility across assets and timeframes, adapting to analyst preferences while remaining consistent in its structure.

Cycle Mode & AMD Profiling

The Forever° Model [Pro+] has been expanded with a cycle-based detection framework that operates alongside the original FVG workflow. This update introduces independent detection modes, real-time SMT evaluation, and AMD cycle profiling built around quarterly market behavior, adding higher-timeframe structural context without changing the model's core logic.

New Detection Modes

Setting: Mode (FVG Mode / Cycle Mode / 6-Hour Cycle Mode)

The Forever Model now supports two independent detection frameworks. Each can be used on its own, depending on whether the analyst prefers inefficiency-based or cycle-based structure.

FVG Mode

The original Forever Model logic. This mode maintains the original workflow and structural requirements. Detection requires:

- HTF Fair Value Gap

- LTF SMT divergence
- CISD confirmation

Cycle Mode

Introduces cycle-based SMT detection built around 90-minute and 6-hour market cycles. Unlike FVG Mode, a Fair Value Gap is not required. A valid setup forms when one correlated asset raids a previous cycle extreme while the comparison asset fails to produce that same move. Detection requires:

- 90-minute cycle SMT divergence
- 6-hour cycle SMT divergence
- CISD confirmation

6-Hour Cycle Mode

Introduces higher-timeframe cycle analysis using 6-hour market cycles, designed to align larger structural shifts with quarterly market behavior. The model evaluates:

- Cycle highs and lows
- SMT divergence
- CISD confirmation

Live SMT Detection

SMT detection has been redesigned to operate in real time. Previous versions required confirmed swing points before SMT could be recognized. The updated model continuously evaluates divergence as price develops, allowing SMT conditions to be identified before swing confirmation occurs.

This provides earlier awareness of developing divergence and cycle inefficiencies.

Enhanced SMT Framework

The model now supports automatic SMT evaluation across two correlated instruments simultaneously. SMT detection:

- Runs automatically
- Tracks divergence between paired assets

- Integrates directly into cycle detection logic

This removes the need for manual SMT monitoring and ensures divergence is evaluated continuously.

AMD Cycle Profiling

The model can plot AMD cycle boxes that visualize how each completed cycle developed, classified according to its quarterly phase.

Show 90m Cycle Boxes

Displays AMD cycle boxes for completed 90-minute cycles. Each box is automatically classified according to its quarterly phase:

- **A** Accumulation
- **M** Manipulation
- **D** Distribution
- **X** Expansion / Reversal / Retracement

These boxes help visualize intraday cycle development and structural progression throughout the session.

Show 6H Cycle Boxes

Displays AMD cycle boxes for completed 6-hour cycles. 6-hour cycle boxes provide higher-timeframe context and can be used to monitor broader market development.

Show Cycles on All TFs

Controls whether cycle boxes are displayed outside their native execution timeframe.

Disabled (Default):

- 5-minute charts display 90-minute cycles
- 15-minute charts display 6-hour cycles

Enabled:

- Both cycle tiers are displayed simultaneously on supported charts

This allows traders to view higher-tier cycle context while maintaining execution focus.

AMD Box Customization

AMD cycle boxes support full visual customization. Users can independently configure colors for each phase:

- Accumulation (A)
- Manipulation (M)
- Distribution (D)
- Expansion / Reversal / Retracement (X)

This allows AMD phases to be adapted to individual chart layouts and color themes.

Live Cycle SMT Visualization

90m SMT Line

Controls the appearance of the SMT divergence line used by the 90-minute cycle model. The SMT line connects previous-cycle and current-cycle extremes when divergence is detected. Users can customize:

- Color
- Line style
- Line width

6H SMT Line

Controls the appearance of the SMT divergence line used by the 6-hour cycle model. This visualization helps identify cycle-level divergence between correlated markets. Users can customize:

- Color
- Line style
- Line width

Quarterly Theory Integration

The Forever Model now incorporates quarterly market behavior into the cycle framework. Cycle boxes are automatically classified into AMD phases based on their position within the broader quarterly delivery sequence. This provides additional context for:

- Session profiling
- Structural development
- Cycle continuation
- Reversal conditions

Automatic Timeframe Alignment

Timeframe alignment has been updated to match the new cycle architecture, allowing the indicator to automatically display the appropriate cycle model without requiring manual configuration. Default pairings now include:

- 5-Minute execution → 90-Minute cycle
- 15-Minute execution → 6-Hour cycle

Order Block Qualification Improvements

Order Block qualification logic has been refined for the cycle mode. The updated framework applies stricter structural requirements before an Order Block can be used for setup generation. These changes are designed to improve consistency across:

- Cycle models
- SMT confirmation
- CISD validation

Analyst Insight:

Cycle Mode lets the model frame setups purely from time-based market cycles and intermarket divergence, useful when price is delivering cleanly without leaving a qualifying Fair Value Gap. Pairing 90-minute and 6-hour cycles with AMD profiling helps contextualize where the current session sits within the broader quarterly delivery sequence.

Concept Definitions

IRL (Internal Range Liquidity): A Fair Value Gap or inefficiency within an established range. Represents areas where delivery may rebalance before continuing.

FVG (Fair Value Gap): A gap between candles where price moved rapidly without overlap. Often revisited before new structure forms.

SMT (Structure/Market Timing Divergence): A dislocation between two assets at the same time, where one makes a lower low or higher high while the other diverges.

CISD (Change in State of Delivery): A lower timeframe candle that sweeps liquidity and closes beyond its open, suggesting structural shift in price behavior.

OB (Order Block): The CISD-confirmed candle, used as a reference structure. May optionally project levels for visual continuity.

ERL (External Range Liquidity): Highs or lows beyond internal range that often serve as delivery objectives following divergence.

CE (Consequent Encroachment): Midpoint of the FVG used to assess how much of an imbalance has been filled.

AMD (Accumulation, Manipulation, Distribution): The cyclical phases used to profile each market cycle. The model also marks X, Expansion / Reversal / Retracement, for the resolving phase.

Cycle (90-Minute / 6-Hour): Time-based market cycles the model uses for cycle-mode SMT detection and AMD profiling, in place of (or alongside) inefficiency-based detection.

Quarterly Theory: The framework that classifies each cycle into AMD phases based on its position within the broader quarterly delivery sequence.

Live SMT: Real-time SMT divergence evaluation as price develops, identified before swing-point confirmation.

Concept Introduction

Forever° Model [Pro+] ($niper) is a clean, structured framework for visualizing internal price behavior. It identifies shifts in market delivery by combining internal liquidity zones, divergence between correlated markets, and lower timeframe orderflow changes. Designed for repeatability, the model helps analysts build confidence through familiarity, not complexity.

Rather than attempting to forecast direction, this model focuses on recognizing recurring patterns in delivery behavior across timeframes. It does not issue alerts or predictions, but instead presents structured visual logic that can support manual analysis.

The model is stable, non-repainting, and built to highlight past setups once formed. It offers flexibility across assets and timeframes, adapting to analyst preferences while remaining consistent in its structure.

Key Capabilities And Features

Internal Range Liquidity (IRL)

Detects fair value gaps and internal inefficiencies that represent areas where price may revisit before continuing.

Smart Money Technique (SMT) Divergence

Compares your active chart with a correlated market to identify divergence in structural highs or lows. This highlights potential delivery dislocations that matter for direction context.

SMT Pair Logic

Manually define a correlated asset, use automatic SMT pair detection, or inverse SMT for negatively correlated relationships.

Change in State of Delivery (CISD)

Detects lower timeframe candles that sweep short term levels and close beyond their open, signalling a shift in delivery regime and marking them as orderblock candidates.

Orderblock and Projections

When CISD is detected, an orderblock candidate is plotted along with optional projections to reflect potential structural reactions.

External Range Liquidity (ERL)

Visualizes swing highs or lows beyond internal structures that often act as delivery objectives following rotations.

Liquidity Sweep Visualization

Highlights recently swept liquidity points that resulted in CISD for additional context.

Cycle Mode (90m / 6H)

Detects setups from time based market cycles rather than fair value gaps. A valid cycle setup forms when one correlated asset raids a previous 90 minute or 6 hour cycle extreme while the comparison asset fails to follow, confirmed by a change in state of delivery.

Live SMT Detection

Evaluates divergence between correlated markets in real time as price develops, surfacing SMT conditions before swing points are confirmed for earlier awareness of developing inefficiencies.

AMD Cycle Profiling

Plots cycle boxes for completed 90 minute and 6 hour cycles, automatically classified into Accumulation, Manipulation, Distribution, and Expansion phases to visualize structural progression through the session.

Quarterly Theory Integration

Classifies each cycle into AMD phases based on its position within the broader quarterly delivery sequence, adding higher timeframe context for session profiling and cycle continuation.

Directional Bias Filter

Choose to show only bullish, bearish, or both types of formations to align with higher timeframe bias or study unidirectional structure.

Model History Control

Adjust how many past formations appear on the chart to support clean live charting or deeper history review up to 40 prior models.

Session Filters and Timezones

Define up to four time blocks for when the model is active, with timezone customization for precise session based filtering.

Information Table

Floating panel shows active parameters including timeframe alignment, bias direction, SMT pair, and session conditions.

Model Markers and Backtest Support

Displays visual markers for past structure outcomes to aid chart review and backtesting.

Alerts

Support for alerts on key development steps such as new internal range tags, SMT confirmation, model activation, orderblock projections, and external range liquidity hits.
